1 Introduction

This thesis focuses on a variation of the $Tur\'{a}n\ problem$ in extremal combinatorics. The fundamental question in extremal hypergraph theory is determining the maximum number of edges in an n-vertex r-uniform graph that does not contain a prescribed r-uniform graph F as a subgraph. These maxima, denoted ex(n, F), are referred to as the extremal numbers or $Tur\'{a}n\ numbers$ for F. One of the cornerstones of extremal graph theory, concerning the case F is a clique, is Tur\'{a}n's Theorem [19]. To state the theorem, we need the $Tur\'{a}n\ graphs$ $T_k(n)$, which denotes a complete multipartite graph with n vertices and k parts of size $\lfloor n/k \rfloor$ or $\lceil n/k \rceil$.

Theorem A (Turán's Theorem). The maximum number of edges in an n-vertex graph containing no clique of order r + 1 is $e(T_r(n))$, with equality only for $T_r(n)$.

Simonovits [5] observed via the Erdős-Stone Theorem [3] that the asymptotic value of ex(n, F) may be obtained whenever F is non-bipartite:

Theorem B (Erdős-Stone Theorem, Simonovits' Theorem). Let F be any graph of chromatic number $r+1 \geq 3$. Then $\operatorname{ex}(n,F) = (1+o(1))T_r(n)$ as $n \to \infty$.

There are a number of proofs of the Erdős-Stone Theorem. A very general framework involves Szemerédi's Regularity Lemma, which may be stated as follows. A pair (U, V) of disjoint sets of vertices in a graph G is called ϵ -regular if for any $X \subseteq U$ and $Y \subseteq V$ of size at least $\epsilon |U|$ and $\epsilon |V|$ respectively, $|e(X,Y)/|X||Y| - e(U,V)/|U||V|| < \epsilon$. The following was proved by Szemerédi [18]:

Theorem C (Szemerédi's Regularity Lemma). For all $\epsilon > 0$, there exist m and M such that for every graph G, there exists a partition (V_1, V_2, \ldots, V_k) of V(G) such that $m \leq k \leq M$ and $|V_1| \leq |V_2| \leq \cdots \leq |V_k| \leq |V_1| + 1$ and all but at most ϵk^2 pairs (V_i, V_j) are ϵ -regular.

The case where F is bipartite is in general wide open, and the order of magnitude of $\operatorname{ex}(n,K_{4,4})$ or $\operatorname{ex}(n,C_8)$ is not known – see Füredi and Simonovits [8] for a history of the bipartite Turán problem. There is also no analog of the above theorems for r-uniform hypergraphs; the asymptotic value of $\operatorname{ex}(n,K_k^r)$ is not known for any $k>r\geq 3$, where K_k^r denotes the complete r-uniform hypergraph on k vertices. The asymptotic value of $\operatorname{ex}(n,K_4^3)$ was conjectured by Turán [19] to be $\frac{5}{9}\binom{n}{3}$, and this remains open despite decades of intensive research.

In this thesis, we investigate closely related problems which we refer to as double Tur'an problems. To describe these problems, let G_1, G_2, \ldots, G_m be graphs with the same vertex

set $V(G_i) = [n]$ for $i \in [m]$. For a graph F, we say that G_1, G_2, \ldots, G_m is double F-free if $E(F) \not\subseteq E(G_i) \cap E(G_j)$ for $1 \le i < j \le m$. In other words, F does not appear in the intersection of any two of the graphs G_i . We call a copy of F in the intersection of two of the graphs G_i a double F. Let $\phi(m, n, F)$ denote the maximum value of $\sum_{i=1}^m e(G_i)$ such that G_1, G_2, \ldots, G_m does not contain a double F. We say that graphs G_1, G_2, \ldots, G_m are induced to mean that every G_i is an induced subgraph of $\bigcup_{i=1}^m G_i$. In other words, if $\{u, v\} \in E(G_i)$ and $u, v \in V(G_j)$, then $\{u, v\} \in E(G_j)$. Let $\phi^*(m, n, F)$ denote the maximum value of $\sum_{i=1}^m e(G_i)$ such that G_1, G_2, \ldots, G_m does not contain a double F and G_1, G_2, \ldots, G_m are induced. Clearly, $\phi^*(m, n, F) \le \phi(m, n, F)$, and the study of $\phi^*(m, n, F)$ and $\phi(m, n, F)$ is motivated by certain hypergraph extremal problems.

1.1 Link graphs and hypergraphs

Apart from the intrinsic interest in studying $\phi(m, n, F)$, a motivation is that $\phi(m, n, F)$ is closely connected to pure hypergraph extremal problems via the notion of $link\ graphs$. Let H be a triple system, that is, a set of three-element subsets of a finite set [n]. These three-element subsets form the edge-set E(H) of H, while V(H) = V is the vertex set of H. For $i \in V(H)$, let H_i denote the $link\ graph$ of i, with $V(H_i) = V(H) \setminus \{i\}$ and $E(H_i) = \{\{j,k\} : \{i,j,k\} \in E(H)\}$. A useful idea in extremal hypergraph theory is to try to reduce an extremal problem for hypergraphs to extremal problems for the link graphs. For instance, a triple system H does not contain three triples on four vertices if and only if all its link graphs are triangle-free.

In the current context, given a graph F, let F^+ denote the triple system with $V(F^+) = V(F) \cup \{x,y\}$ and $E(F^+) = \{e \cup \{x\}, e \cup \{y\} : e \in E(F)\}$. Then $\phi(n,n,F)$ and $\operatorname{ex}(n,F^+)$ are intimately related: if H is an F^+ -free triple system with vertex set [n], then clearly the link graphs H_1, H_2, \ldots, H_n are double F-free, which implies $\operatorname{ex}(n,F^+) \leq \phi(n,n,F)$. This relates the double Turán problem to hypergraph extremal problems.

Now let G be the graph consisting of all pairs contained in triples in F^+ . The generalized Turán problem asks for the maximum number $\operatorname{ex}(n,G,K_3)$ of triangles in a graph H with vertex set [n] that does not contain G. This problem was studied by Alon and Shikhelman [1] and Kostochka, Mubayi and Verstraete [10, 12, 14]. This problem is related to $\phi^*(n, n, F)$ as follows: define $H_i = \{\{j, k\} : \{i, j\}, \{j, k\}, \{i, k\} \in E(H)\}$. Then H_1, H_2, \ldots, H_n are induced and double F-free, so $\phi^*(n, n, F) \geq \operatorname{ex}(n, G, K_3)$. This relates the induced double Turán problem to extremal problems for triangles in graphs.

1.2 Main results: the induced case

The determination of $\phi^*(m, n, F)$ turns out to be fairly straightforward when F is a non-bipartite graph, as the extremal objects are simply m copies of the same extremal graph for F:

Theorem 1. For $r \geq 3$, there exists $n_0(r)$ such that if $n \geq n_0(r)$ and F is a graph of chromatic number r, then for all $m \geq 3$,

$$\phi^*(m, n, F) = m \cdot ex(n, F),$$

with equality only for identical extremal n-vertex F-free graphs.

In the case $F = K_r$, we shall see the theorem is true for all $n \geq 3$:

Theorem 2. Let $m, n, r \geq 3$. Then $\phi^*(m, n, K_r) = m \cdot e(T_{r-1}(n))$ with equality for induced K_r -free graphs G_1, G_2, \ldots, G_m only if $G_1 = G_2 = \cdots = G_m = T_{r-1}(n)$.

In the case F is a bipartite graph, even determining the order of magnitude of $\phi^*(m, n, F)$ appears to be difficult. In fact, we do not even know the order of magnitude of $\phi^*(m, n, P)$ when P is a path with two edges. In this thesis, we propose the following very broad conjecture:

Conjecture A. Let F be any non-empty graph and $m, n \ge 1$. Then

$$\phi^*(m, n, F) = \Theta(m \cdot \operatorname{ex}(n, F) + n^2).$$

It is clear that a single complete graph K_n does not contain a double F, and neither do identical copies G_1, G_2, \ldots, G_m of an extremal n-vertex F-free graph. Thus we have the trivial lower bound

$$\phi^*(m, n, F) \ge \max\left\{ \binom{n}{2}, m \cdot \operatorname{ex}(n, F) \right\}.$$

This conjecture is true when F is non-bipartite, by Theorem 1. If F is bipartite, then upper bounds on $\phi^*(m, n, F)$ are more difficult to come by, especially when m is large. For instance, we know

$$ex(n, K_{2,2,2}, K_3) \le \phi^*(n, n, K_{2,2}),$$

and so Conjecture A implies that an n-vertex graph not containing the octahedron graph has $O(n^{5/2})$ triangles. In fact, it is also the case that $\exp(2n, K_{2,2,2}, K_3) \ge \phi^*(n, n, K_{2,2})$: if we have double $K_{2,2}$ -free induced graphs G_1, G_2, \ldots, G_n with vertex set [n], then let H be

the graph with V(H) = [2n] consisting of all triangles with vertex set $\{i, j, k\}$ such that $n < k \le 2n$ and $\{i, j\} \in E(G_k)$. The graph H is $K_{2,2,2}$ -free and $|E(H)| = \sum_{i=1}^{n/2} e(G_i)$. Similarly, we have

$$ex(n, K_{1,2,2}, K_3) \le \phi^*(n, n, K_{1,2})$$

and so Conjecture A implies that an n-vertex graph not containing the octahedron graph has $O(n^2)$ triangles, which is conjectured by Mubayi and Verstraete [14]. The conjecture proposes more generally that if F is a tree, then $\phi^*(n, n, F) = O(n^2)$. In fact, it is possible to prove the following theorem using the $removal\ lemma$ as in [12] as well as a construction for $\phi(n, n, P)$ in this work:

Theorem 3. Let P be a path with two edges. Then $\phi(n, n, P) = \Omega(n^{5/2})$, whereas $\phi^*(n, n, P) = o(n^{5/2})$, as $n \to \infty$. In particular,

$$\lim_{n \to \infty} \frac{\phi^*(n, n, P)}{\phi(n, n, P)} = 0.$$

If M is a matching with two edges, and M^+ is the graph obtained from two copies of K_4 sharing one edge by removing that edge, then $\operatorname{ex}(n,M^+,K_3) \leq \phi^*(n,n,M)$. If F is the triple system consisting of all four triangles in M^+ , then Füredi [7] showed $\operatorname{ex}(n,M^+) = O(n^2)$, answering a conjecture of Erdős [4]. It is possible to adapt Füredi's proof to give $\phi^*(n,n,M) = O(n^2)$, so in this case, $\operatorname{ex}(n,M^+,K_3) = \Theta(\phi^*(n,n,M))$. For improvements of the constant factor, see Mubayi and Verstraete [13] and Pikhurko and Verstraete [15]. We shall see that if F is bipartite and m is not too large relative to n, then Conjecture A is also true.

1.3 Main results: the non-induced case

Determining $\phi(m, n, F)$ even when F is a complete graph is challenging. The forth theorem we give is well-suited to the case of bipartite graphs, and is due to Wilson:

Theorem 4. Let F be a graph. If there exists an extremal F-free n-vertex graph with maximum degree at most $n^{1/2}/m^2$, then

$$\phi(m, n, F) = \binom{n}{2} + \binom{m}{2} ex(n, F).$$

Since $\binom{n}{2} + m - 1 \le \phi^*(m, n, F) \le \phi(m, n, F)$ for any graph F with at least two edges, this theorem shows $\phi^*(m, n, F) = (1 + o(1))\binom{n}{2}$ whenever the conditions on m in the theorem are satisfied. In particular, if P is the path with two edges, and $m = o(n^{1/4})$ as $n \to \infty$, then

for $n \geq 2$,

$$\binom{n}{2} + m - 1 \le \phi^*(m, n, P) \le \phi(m, n, P) = \binom{n}{2} + \binom{m}{2} \left\lfloor \frac{n}{2} \right\rfloor.$$

When F is bipartite, the value of $\phi(m, n, F)$ for larger m appears to be difficult to determine. We investigate the case F = P more closely.

Theorem 5. Let P be the path with two edges. Then as $n \to \infty$,

$$\phi(m, n, P) = \begin{cases} \left(\frac{1}{2} + o(1)\right) n^2, & \sqrt{n}/m \to \infty \\ \Theta(n^2), & m = \Theta(\sqrt{n}) \\ \left(\frac{1}{2} + o(1)\right) m n^{3/2}, & \sqrt{n} < m \le n \\ \left(\frac{1}{2} + o(1)\right) \sqrt{m} n^2, & n < m \le n^2 \\ \Theta(n^3), & m = \Theta(n^2) \\ (1 + o(1)) m n, & m/n^2 \to \infty \end{cases}$$

Interestingly, while Conjecture A proposes $\phi^*(m, n, P) = O(n^2 + mn)$ for all $m, n \ge 1$, the above theorem shows $\phi(m, n, P)$ is much larger, of order at least $mn^{3/2}$ when $m \ge \sqrt{n}$.

Our first theorem on $\phi(m, n, F)$ for non-bipartite graphs F uses the notion of supersaturation – see Erdős and Simonovits [6]. We determine the asymptotic value of $\phi(m, n, F)$ as $m \to \infty$ when F is a non-bipartite graph:

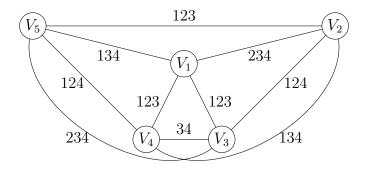

Theorem 6. Let $n \geq 1$ and let F be a non-bipartite graph. Then as $m \to \infty$,

$$\phi(m, n, F) = (1 + o(1))m \cdot ex(n, F).$$

The next result we present concerns non-bipartite graphs. To state the theorem, we require the notion of k-color Ramsey numbers. Define $R_k(r)$ to be the k-color Ramsey number for the complete graph K_r : that is, the minimum N such that there exists a monochromatic F in any coloring of $E(K_N)$ with k colors. Suppose we have a coloring $c: E(K_N) \to 2^{[m]}$ for some $N < R_k(r)$ where $k \leq {m \choose 2}$ and $|c(u,w)| \geq 2$ for all $\{u,w\} \in E(K_N)$. For $i \in [m]$, let $H_i = \{\{u,w\} \in E(K_N) : i \in c(u,w)\}$. Then H_1, H_2, \ldots, H_m are double K_r -free. If we replace the vertices of K_N with disjoint sets $V_w : w \in V(K_N)$ whose sizes add up to n, and then let $G_1 = K_n$ and

$$G_i = \{\{x, y\} : (x, y) \in V_u \times V_w, i \in c(u, w)\}$$

then G_1, G_2, \ldots, G_m is also double K_r -free. We call G_1, G_2, \ldots, G_m an (m, n, k)-blowup.

Example of an (4, n, 5)-blowup.

Let f(m, n, r) denote the maximum of $e(H_1) + e(H_2) + \cdots + e(H_m)$ such that H_1, H_2, \ldots, H_m is an (m, n, k)-blowup for some $k \leq {m \choose 2}$. This turns out to be exactly the construction which determines $\phi(m, n, F)$ when F is a complete graph:

Theorem 7. Let $r \geq 2$ and $m, n \geq 1$. Then

$$\phi(m, n, K_r) = f(m, n, r).$$

While computing f(m, n, r) is a finite calculation, the Ramsey number $R_k(r)$ unfortunately appears to be intractable in general; it is known that $R_2(3) = 6$ and $R_3(3) = 17$ and $R_2(4) = 18$, but no further multicolor Ramsey numbers are known [2, 11]. In the special case r = m = 3, the following holds:

Theorem 8. For all $n \geq 1$,

$$\phi(3, n, K_3) = \binom{n}{2} + \left\lfloor \frac{n^2}{2} \right\rfloor.$$

1.4 Definitions and Notations

Denote the set of first n positive integers as $[n] = \{1, 2, ..., n\}$. Given a set X, we denote 2^X as the power set of X.

Let G = (V, E) be a graph. Let V(G) denote the vertex set and E(G) denote the edge set of G. Let e(G) = |E(G)| be the number of edges in G. For vertex $v \in V(G)$, we denote by $N_G(v) = \{u \in V(G) : \{u, v\} \in E(G)\}$ the neighborhood of v.

Given two graphs G_1, G_2 , we denote $G_1 \cup G_2$ as the graph on $V(G_1) \cup V(G_2)$ with edge set $E(G_1 \cap G_2) = E(G_1) \cup E(G_2)$. Let s

In this thesis, we reserve n to denote the number of vertices in a graph. We call a n-vertex complete graph K_n , and a complete bipartite graph $K_{a,b}$, where a,b are the sizes of its parts. Given graph G,H, define G+H as the graph fully connecting G,H, i.e. $V(G+H)=V(G)\cup V(H)$ and $E(G+H)=E(G)\cup E(H)\cup \{\{u,v\}:u\in V(G),v\in V(H)\}.$

Given graphs G and F, we say that G is F-free if G does not contain F as a subgraph. We denote $\operatorname{ex}(n, F)$ to be the maximum possible number of edges an F-free graph on n vertices, and we call a F-free graph achieving this maximum an extremal graph for F. Let v be a vertex from G_1, G_2, \ldots, G_m . Unless otherwise specified, we denote d(v) as the sum of the degree of v over all G_i .

2 The induced double Turán problem

We prove the theorems for $\phi^*(m, n, F)$ in this chapter. In particular, the main theorem we prove is Theorem 1 for general non-bipartite graphs F and in the special case of cliques. We will first introduce two observations that significantly simplify the problem.

The first observation is that the determination of $\phi^*(m, n, F)$ can be reduced down to the case of two graphs, which is stated in the following lemma:

Lemma 9. Let $n, m, k \geq 2$ with $m \geq k$, F be some graph. Then

$$\phi^*(m, n, F) \le \frac{m}{k} \cdot \phi^*(k, n, F).$$

Moreover, let G_1, \ldots, G_m be induced double F-free graphs on [n] and suppose $\sum_{i=1}^k e(G_i) = \phi^*(k, n, F)$ only if $G_1 = \cdots = G_k$. Then $\sum_{i=1}^m e(G_i) = \phi^*(m, n, F)$ only if $G_1 = \cdots = G_m$.

Proof. Let G_1, \ldots, G_m be induced double F-free graphs on [n]. Put $G_{i+m} = G_i$ for all $i \in [m]$. Then

$$\sum_{i=1}^{m} e(G_i) = \frac{1}{k} \sum_{i=1}^{m} [e(G_i) + \dots + e(G_{i+k-1})] \le \frac{1}{k} \sum_{i=1}^{m} \phi^*(k, n, F) = \frac{m}{k} \cdot \phi^*(k, n, F),$$

which establishes the upper bound. The lower bound follows from the construction with $G_1 = \cdots = G_m$ to be *n*-vertex extremal graphs for F.

Now suppose $\sum_{i=1}^{m} e(G_i) = (m/k)\phi^*(k, n, F)$ and $G_1 \neq G_2$. By assumption $\sum_{i=1}^{k} e(G_i) < \phi^*(k, n, F)$. But then $\sum_{i=1}^{k} e(G_{i+j}) > \phi^*(k, n, F)$ for some $j \geq 1$, contradiction.

Now that we may determine $\phi^*(m, n, F)$ by examining $\phi^*(m, n, F)$, the second observation is

that $\phi^*(m, n, F)$ can be further reduced to a finite optimization problem on a single variable. To state the lemma, we introduce the following construction function:

Definition 10. For $n \ge t \ge 1$ and F some graph, define

$$C(n,t,F) := \binom{n-t}{2} + (n-t)t + 2\operatorname{ex}(t,F).$$

The construction described by C(n, t, F) are graphs G_1, G_2 on [n], such that G_2 is a t-vertex extremal graph for F and $G_1 = G_2 + K_{n-t}$.

Lemma 11. Let F be some graph. For $n \geq 1$,

$$\phi^*(2, n, F) = \max_{0 \le t \le n} \mathcal{C}(n, t, F).$$

Moreover, the equality holds for graphs G_1, G_2 on [n] only if G_1, G_2 are the construction described by $C(n, t_{max}, F)$, where $t_{max} \in [n]$ is a maximizer for C(n, t, F).

Proof. Let G_1, G_2 be induced double F-free graphs on [n]. Put $T = V(G_1) \cap V(G_2)$, t = |T|, $s = |V(G_1) \setminus T|$, and $n - t - s = |V(G_2) \setminus T|$. Note that $t, s \in \mathbb{Z}_{\geq 0}$. Since G_1, G_2 are induced subgraphs of $G_1 \cup G_2$, we have $G_1[T] = G_2[T] = G_1 \cap G_2$. But then $G_1 \cap G_2$ is F-free, so $e(G_1[T]) = e(G_2[T]) \leq \operatorname{ex}(t, F)$. Notice there can be at most t(n - t) edges between T and $(V(G_1) \cup V(G_2)) \setminus T$. Since $G[V(G_1) \setminus T] \leq \binom{s}{2}$ and $G[V(G_2) \setminus T] \leq \binom{n-t-s}{2}$,

$$e(G_1) + e(G_2) \le {s \choose 2} + {n-s-t \choose 2} + t(n-t) + 2ex(t, F).$$

But then $\binom{n-t}{2} > \binom{s}{2} + \binom{n-t-s}{2}$ for 0 < s < n-t, so

$$e(G_1) + e(G_2) \le {n-t \choose 2} + (n-t)t + 2ex(t,F) = \mathcal{C}(n,t,F).$$

This establishes the upper bound. From this we also know that $e(G_1) + e(G_2) = \mathcal{C}(n, t, F)$ only if G_1, G_2 are the construction described by $\mathcal{C}(n, t, F)$. The result now follows.

2.1 Proof of Theorem 2

By Lemma 9, it suffices to prove the theorem for m=3. Let G_1, G_2, G_3 be induced double K_r -free graphs, such that $e(G_1) + e(G_2) + e(G_3) = \phi^*(3, n, K_r)$. We may assume $e(G_1) \ge e(G_2) \ge e(G_3)$, and we already know $\phi^*(3, n, K_r) \ge 3 \exp(n, K_r)$. Consequently, we must have $e(G_1) + e(G_2) \ge 2 \exp(n, K_r)$. Since G_1, G_2, G_3 are induced and $e(G_1) + e(G_2) + e(G_3) \ge 2 \exp(n, K_r)$.

 $3ex(n, K_r)$, it suffices to show that $G_1 = G_2 = T_{r-1}(n)$. In particular, we will use Lemma 11 to show that G_1, G_2 is an extremal configuration without containing a double K_r .

Let $t = |V(G_1 \cap G_2)|$. By Turán's Theorem,

$$ex(t, K_r) - ex(t - 1, K_r) = e(T_{r-1}(t)) - e(T_{r-1}(t - 1)) = t - \left[\frac{t}{r - 1}\right].$$

It immediately follows that

$$C(n, t, K_r) - C(n, t - 1, K_r) = -t + 1 + 2[ex(t, K_r) - ex(t - 1, K_r)] = t + 1 - 2\left[\frac{t}{r - 1}\right].$$
(1)

For $r \geq 4$, $C(n, t, K_r)$ is strictly increasing on t, so by Lemma 11,

$$\phi^*(2, n, K_r) = \mathcal{C}(n, n, K_r) = 2\operatorname{ex}(n, K_r) = e(G_1) + e(G_2)$$

and $G_1 = G_2 = T_{r-1}(n)$, as desired.

Now suppose r=3. Equation (1) shows that $C(n,t,K_r)$ is non-decreasing on t and $C(n,t,K_r) > C(n,t,K_r)$ for even t. By Lemma 11, we now have

$$\phi^*(2, n, K_r) = \max[\mathcal{C}(n, n, K_r), \mathcal{C}(n, n - 1, K_r)] = 2\operatorname{ex}(n, K_r) = e(G_1) + e(G_2),$$

and either $G_1 = G_2 = T_{r-1}(n)$, or $G_2 = T_{r-1}(n-1)$ and $G_1 = G_2 + K_1$. If the latter case is true, then $e(G_3) \ge \operatorname{ex}(n, F) > e(G_2)$, and this contradiction completes the proof.

2.2 Proof of Theorem 1

If F is a graph of chromatic number $r+1 \geq 3$, then Theorem B shows $\operatorname{ex}(n, F) = (1 + o(1))\operatorname{ex}(n, K_{r+1})$ as $n \to \infty$. In this section, we prove Theorem 1.

Proof of Theorem 1. By Lemma 9, it suffices to prove the theorem for m=3. Let G_1, G_2, G_3 be induced double F-free graphs, such that $e(G_1) + e(G_2) + e(G_3) = \phi^*(3, n, F)$. We may assume $e(G_1) \geq e(G_2) \geq e(G_3)$, and we already know $\phi^*(3, n, F) \geq 3 \operatorname{ex}(n, F)$. Consequently, we must have $e(G_1) + e(G_2) \geq 2 \operatorname{ex}(n, F)$. Since G_1, G_2, G_3 are induced and $e(G_1) + e(G_2) + e(G_3) \geq 3 \operatorname{ex}(n, F)$, it suffices to show that $G_1 = G_2$ are n-vertex F-free extremal graphs. In particular, we will use Lemma 11 to show that G_1, G_2 is an extremal configuration without containing a double F.

Let $t = |V(G_1 \cap G_2)|$. If $t < \sqrt{n}$, then

$$2\mathrm{ex}(n,F) \ge 2e(T_{r-1}(n)) \ge 2\left\lfloor \frac{n^2}{4} \right\rfloor \ge \binom{n}{2} + \binom{\sqrt{n}}{2} > \mathcal{C}(n,t,F).$$

Thus $t \geq \sqrt{n}$. But then for large enough t, any extremal t-vertex F-free graph contains a spanning complete (r-1)-partite subgraph $T_{r-1}(t)$, so we may add $\operatorname{ex}(t-1,F) - e(T_{r-1}(t-1))$ egdes to $T_{r-1}(t)$ and still avoid F as a subgraph. Hence for large enough t, we have $\operatorname{ex}(t,F) \geq \operatorname{ex}(t-1,F) - e(T_{r-1}(t-1)) + e(T_{r-1}(t))$, and so

$$ex(t, F) - ex(t - 1, F) \ge e(T_{r-1}(t)) - e(T_{r-1}(t - 1)) \ge t - \left\lceil \frac{t}{r - 1} \right\rceil.$$

It immediately follows that

$$C(n, t, F) - C(n, t - 1, F) = -t + 1 + 2[ex(t, F) - ex(t - 1, F)] \ge t + 1 - 2\left[\frac{t}{r - 1}\right]. \quad (2)$$

For $r \geq 4$, C(n, t, F) is strictly increasing on t, so by Lemma 11,

$$\phi^*(2, n, F) = \mathcal{C}(n, n, F) = 2\operatorname{ex}(n, F) = e(G_1) + e(G_2),$$

and $G_1 = G_2$ are *n*-vertex *F*-free extremal graphs, as desired.

Now suppose r = 3. Equation (2) shows that C(n, t, F) is strictly increasing for even t and $C(n, t, F) \ge C(n, t - 1, F)$ for odd t. By Lemma 11, we now have

$$\phi^*(2, n, F) = \max[\mathcal{C}(n, n, F), \mathcal{C}(n, n - 1, F)] = 2\mathrm{ex}(n, F) = e(G_1) + e(G_2),$$

and either $G_1 = G_2$ are *n*-vertex extremal *F*-free graphs, or G_2 is an (n-1)-vertex extremal *F*-free graph and $G_1 = G_2 + K_1$. If the latter case is true, then $e(G_3) \ge ex(n, F) > e(G_2)$, and this contradiction completes the proof.

2.3 Proof of Theorem 3

According to Theorem 5, $\phi(n, n, P) = (1/2 + o(1))n^{5/2}$. So to prove Theorem 3, it is sufficient to show $\phi^*(n, n, P) = o(n^{5/2})$.

Let G_1, G_2, \ldots, G_n be induced and double P-free and let $\epsilon > 0$. Let $d_i(v)$ be the degree of vertex v in the graph G_i . Let I be the set of pairs (i, v) such that $d_i(v) \geq \sqrt{n}/\epsilon + 1$. Since

 G_1, G_2, \ldots, G_n do not contain a double P,

$$\sum_{(i,v)\in I} \binom{d_i(v)}{2} \le n^3.$$

The maximum possible value of $\sum_{(i,v)\in I} d_i(v)$ subject to this constraint is when $d_i(v) = \sqrt{n}/\epsilon + 1$ for all (i,v), in which case $|I| \leq 2\epsilon^2 n^2$ and so

$$\sum_{(i,v)\in I} d_i(v) \le (2\epsilon^2 n^2) \cdot \left(\frac{\sqrt{n}}{\epsilon} + 1\right) = 3\epsilon n^{5/2}$$

for large enough n. Remove all edges of G_i on vertex v such that $(i, v) \in I$. The total number of edges removed is at most $3\epsilon n^{5/2}$. Let G'_1, G'_2, \ldots, G'_n be the remaining subgraphs of G_1, G_2, \ldots, G_n . If $e(G'_i) \leq \epsilon n^{3/2}$, then remove all edges of G'_i . The number of edges removed in this process is at most $\epsilon n^{5/2}$. The remaining graphs $G''_1, G''_2, \ldots, G''_m$ have each at least $\epsilon n^{3/2}$ edges and maximum degree at most \sqrt{n}/ϵ . In particular, each G''_i contains a matching M_i of size at least $\epsilon^2 n/2$. If $m \leq \epsilon n$, then

$$\sum_{i=1}^{n} e(G_i) \le 4\epsilon n^{5/2} + \sum_{i=1}^{m} e(G_i'') \le 4\epsilon n^{5/2} + \phi(m, n, P) \le 5\epsilon n^{5/2}$$

by Theorem 5. If $m > \epsilon n$, then we apply Szemerédi's Regularity Lemma to find, for some $\delta > 0$ depending only on ϵ , a matching say M_1 in G_1'' such that for some pair of set $X, Y \subseteq V(M_1)$ of size at least δn each, there is a set E of at least $\delta^3 n^2$ edges $\{x,y\}$ of $G_1'' \cup G_2'' \cup \cdots \cup G_m''$ such that $x \in X$ and $y \in Y$. Since G_1'' is induced, $E \subseteq E(G_1)$. In particular, there are at least $\delta^5 n^3/4$ copies of P in G_1 . We can repeat the argument in the remaining graphs $G_i'' : i \in [2, m]$ to get say M_2 in G_2'' as above, which gives $\delta^5 n^3/4$ copies of P in G_2 . If we do this $4\delta^{-5}$ times, then we have found n^3 copies of P in the first $4\delta^{-5}$ graphs, and two of them have the same edge-set. We conclude $\sum_{i=1}^n e(G_i) \leq 5\epsilon n^{5/2}$ if n is large enough. Since ϵ is arbitrary, we are done.

3 The non-induced double Turán problem

In this section, we prove our main theorems on $\phi(m, n, F)$.

3.1 Proof of Theorem 6

We need the following *saturation theorem*, which may be found in [6].

Proposition 12. Let F be any non-empty graph with k vertices. For all $\epsilon > 0$, there exists $\delta > 0$ such that if G is any n-vertex graph with $\exp(n, F) + \epsilon n^2$ edges, then G contains δn^k copies of F.

Proof of Theorem 6. Let k = |V(F)| and let $\epsilon > 0$. Let G_1, G_2, \ldots, G_m be double F-free. Reorder G_1, G_2, \ldots, G_m so that $e(G_i) \ge \operatorname{ex}(n, F) + \epsilon n^2$ for $1 \le i \le \ell$ and $e(G_i) < \operatorname{ex}(n, F) + \epsilon n^2$ for $\ell < i \le m$. Then each $G_i : 1 \le i \le \ell$ contains at least δn^k copies of F, by Proposition 12. On the other hand, there are at most n^k copies of F such that $F \subseteq G_i$ for some $i \in [m]$. Therefore $\ell \le 1/\delta$ and

$$\sum_{i=1}^{m} e(G_i) = \sum_{i=1}^{\ell} e(G_i) + \sum_{i=\ell+1}^{m} e(G_i)$$

$$\leq \frac{1}{\delta} \binom{n}{2} + (m-\ell) \operatorname{ex}(n, F) + (m-\ell) \epsilon n^2$$

$$\leq m \cdot \operatorname{ex}(n, F) + \epsilon m n^2 + \frac{1}{\delta} \binom{n}{2}.$$

Since F is not bipartite, $\operatorname{ex}(n,F) = \Theta(n^2)$ and so $\phi(m,n,F) \leq m \cdot \operatorname{ex}(n,F) + (\epsilon+1/\delta m)mn^2$. Since ϵ was arbitrary and δ is a constant depending only on ϵ , we conclude $\phi(m,n,F) \leq (1+o(1))m \cdot \operatorname{ex}(n,F)$ as $m \to \infty$.

Let F be a bipartite graph with $k \geq 2$ vertices and $j \geq 1$ edges. A strong version of a conjecture of Simonovits [16, 17] would suggest that for all $\epsilon > 0$, there exists $\delta > 0$ such that every n-vertex graph G with at least $p\binom{n}{2}(1+\epsilon)\mathrm{ex}(n,F)$ edges contains at least $\delta p^{j}n^{k}$ copies of F. For instance, this is known to be true whenever the asymptotic behavior of $\mathrm{ex}(n,F)$ is known, which includes the case $F = K_{2,t}$. If F is bipartite and $m \cdot \mathrm{ex}(n,F)/n^{2} \to \infty$ as $m,n\to\infty$, then this conjecture with the same proof as above shows $\phi(m,n,F)=(1+o(1))m\cdot\mathrm{ex}(n,F)$. When F contains a cycle, then there exists $\alpha>0$ such that $\mathrm{ex}(n,F)\geq n^{1+\alpha}$ for large enough n. Thus, we conclude that if F contains a cycle and the Simonovits conjecture is true for F, then $\phi(m,n,F)=(1+o(1))m\cdot\mathrm{ex}(n,F)$ for $m\geq n$ and $n\to\infty$. In particular, this shows $\phi(m,n,K_{2,t})=(1+o(1))m\cdot\mathrm{ex}(n,F)$ for $m\geq n$ as $n\to\infty$.

We also present a weaker version of the above theorem that holds for all graphs F, which adopts a similar proof.

Proposition 13. Let $n, k \ge 1$ and let F be a graph with k vertices. If $m \cdot \operatorname{ex}(n, F)/n^k \to \infty$, then

$$\phi(m, n, F) = (1 + o(1))m \cdot ex(n, F),$$

as $m \to \infty$.

Proof. Let G_1, G_2, \ldots, G_m be double F-free. Write $e(G_i) = \operatorname{ex}(n, F) + t_i$ for each $i \in [m]$. Reorder G_1, \ldots, G_m so that $e(G_i) > \operatorname{ex}(n, F)$ for $1 \le i \le \ell$ and $e(G_i) \le \operatorname{ex}(n, F)$ for $\ell < i \le m$. Then each $G_i : 1 < i \le \ell$ contains at least t_i copies of F, and so there are $T = \sum_{i=1}^{\ell} t_i$ copies of F over all G_i . But then there are at most n^k copies of F such that $F \subseteq G_i$ for some $i \in [m]$, so $T \le n^k = o(m) \cdot \operatorname{ex}(n, F)$. It now follows that

$$\sum_{i=1}^{m} e(G_i) \le T + m \cdot ex(n, F) = (1 + o(1))m \cdot ex(n, F).$$

3.2 Proof of Theorem 4

We first show that for all $m, n \ge 1$ and graph F,

$$\phi(m, n, F) \le \binom{n}{2} + \exp(n, F) \binom{m}{2}.$$

Thereafter, we show that if there is an extremal F-free graph with maximum degree at most $n^{1/2}/m^2$, then the above bound is tight.

Proof of the upper bound. For $S \subseteq [m]$, let E_S denote the set of edges that are contained in exactly $\{G_i\}_{i\in S}$. Then

$$\sum_{i=1}^{m} e(G_i) = \sum_{S \subseteq [m]} |S| |E_S| \le \binom{n}{2} + \sum_{S \subseteq [m], |S| \ge 2} (|S| - 1) |E_S|.$$

Let $A_S = \bigcup_{T \supseteq S} E_T$, i.e., the set of edges that are contained in all G_i with $i \in S$. When $|S| \ge 2$, the edge set A_S is F-free and thus

$$\sum_{T\supseteq S} |E_T| \le \operatorname{ex}(n, F).$$

Hence,

$$\sum_{\substack{S \subseteq [m] \\ |S| \ge 2}} (|S| - 1)|E_S| = \sum_{\substack{S \subseteq [m], T \subseteq S \\ |S| = 2}} \sum_{\substack{(|T| - 1)|E_T| \\ 2}} \frac{(|T| - 1)|E_T|}{\binom{|T|}{2}} \le \sum_{\substack{S \subseteq [m], T \subseteq S \\ |S| = 2}} \sum_{|T| \le 1} |E_T| \le \binom{m}{2} \exp(n, F),$$

as each $T \in [m]$ with $|T| \ge 2$ is counted $\binom{|T|}{2}$ times in total and $|T| - 1 \le \binom{|T|}{2}$. This proves the upper bound.

Proof of the lower bound. We need to show there exists a construction such that the graph with edge set E_S is an extremal F-free graph, for all $S \subseteq [m]$ of size 2. Let $M = {m \choose 2}$ and H_1, \ldots, H_M be copies of an extremal F-free graph on n vertices such that H_i with maximum degree $\Delta \leq n^{1/2}/m^2$ for all $i \in [m]$. It suffices to show that we can embed each H_i onto [n] such that their edge sets are pairwise disjoint. We begin by an arbitrary embedding of each H_i and iteratively decrease the number of intersecting edges. Define a (u, v, i)-swap by swapping the embedding of vertex u and v of H_i , i.e. replacing each edge $\{u, w\} \in E(H_i)$ with the edge $\{u, w\}$ and each edge $\{v, w\} \in E(H_i)$ with the edge $\{v, w\}$. This preserves the type of isomorphism of H_i . Given a vertex v, let $N(v) = N_{H_1}(v) \cup \cdots \cup N_{H_M}(v)$. Suppose there exists an intersecting edge $\{u, w\} \in E(H_i) \cap E(H_j)$. Since $|N(u)| \leq M \cdot \Delta \leq n^{1/2}/2$, $|N(u) \cup N(N(u))| \leq \Delta + \Delta(\Delta - 1) \leq n/4$ so there exists a vertex $v \notin N(u) \cup N(N(u))$. Since $N(u) \cap N(v) = \emptyset$, performing a (u, v, i)-swap reduces the number of intersecting edges. The result now follows from iterating this process.

3.3 Proof of Theorem 5

Let G_1, \ldots, G_m be graphs on [n] not containing a double P. We first show the following claims:

Claim 1.
$$\phi(m, n, P) \le mn(1 + \sqrt{4n^2/m + 1})/4$$
.

Proof. Since there is no double P in G_1, G_2, \ldots, G_m ,

$$\sum_{i=1}^{m} \#\{P \subseteq G_i\} \le \#\{P \subseteq K_n\}.$$

For all G_i , each vertex v in G_i along with two of its neighbors form one unique P, so

$$\#\{P \subseteq G_i\} = \sum_{v \in V(G_i)} {d_{G_i}(v) \choose 2}.$$

By Jensen's inequality,

$$\sum_{v \in V(G_i)} {d_{G_i}(v) \choose 2} \ge n {\sum_{v \in V(G_i)} d_{G_i}(v)/n \choose 2} = n {2e(G_i)/n \choose 2} \ge \frac{2(e(G_i))^2}{n} - e(G_i).$$

On the other hand, since each three vertices in G can form at most three P's,

$$\#\{P \subseteq K_n\} \le 3 \binom{n}{3} \le \frac{n^3}{2}.$$

Combining the above inequalities yields and using Jensen's inequality once more yields

$$\frac{2m}{n} \left(\frac{1}{m} \sum_{i=1}^{m} e(G_i) \right)^2 - \sum_{i=1}^{m} e(G_i) \stackrel{\text{Jensen}}{\leq} \sum_{i=1}^{m} \frac{2(e(G_i))^2}{n} - e(G_i) \leq \frac{n^3}{2}.$$

Solving the quadratic equation gives

$$\sum_{i=1}^{m} e(G_i) \le mn \cdot \frac{1 + \sqrt{4n^2/m + 1}}{4}.$$

This proves the claim.

Claim 2. $\phi(m, n, P) \leq (mn^{3/2} + n^2)/2$.

Proof. For each vertex $u \in [n]$, define H_u as the $m \times n$ bipartite graph with edge set $E(H_u) := \{\{v,i\} : \{u,v\} \in E(G_i)\}$. If H_u contains a quadrilateral $\{v,i\}, \{v,j\}, \{w,i\}, \{w,j\}$, then $\{u,v\}, \{u,w\}$ form a double P in $G_i \cap G_j$, contradiction. Thus we conclude that H_u is quadrilateral-free, and therefore $e(H_u) \leq m\sqrt{n} + n$, by the Kővari-Sós-Turán Theorem [9]. It now follows that

$$\sum_{i=1}^{m} e(G_i) = \frac{1}{2} \sum_{u \in V(G)} e(H_u) \le \frac{1}{2} (mn^{3/2} + n^2).$$

This proves the claim.

Claim 2 along with the construction of one complete graph now yield the desired bounds for $m \leq \sqrt{n}$. On the other hand, Claim 1 along with the construction of m extremal graphs for P yield the desired bounds for $m = \Theta(n^2)$. The bound for the case for $m/n^2 \to \infty$ follows from Proposition 13.

Thus it remains to show that $\phi(m, n, P) \ge (1/2 + o(1))mn^{3/2}$ for $\sqrt{n} < m \le n$ and $\phi(m, n, P) \ge (1/2 + o(1))\sqrt{m}n^2$ for $n < m \le n^2$.

We first prove the case $\sqrt{n} \leq m \leq n$. Suppose G_1, G_2, \ldots, G_n are graphs on [n] containing no double P and $\sum_{i=1}^n e(G_i) \geq (1/2 + o(1))n^{5/2}$, with $e(G_1) \geq e(G_2) \geq \cdots \geq e(G_n)$. Then G_1, G_2, \ldots, G_m are graphs with no double P and $\sum_{i=1}^m e(G_i) \geq (1/2 + o(1))mn^{3/2}$. Hence, it suffices to prove the case for m = n.

Consider a finite projective plane with n points and n lines, with prime q chosen so that $n = (1 + o(1))(q^2 + q + 1)$ as $q \to \infty$. Let $S_1, \ldots, S_n \subseteq [n]$ be the n lines of the projective plane. Note that each line S_i contains q + 1 points, and the intersection of any two distinct lines S_i, S_j contains $|S_i \cap S_j| = 1$ point.

Define G_1, \ldots, G_n to be graphs on [n], each with edge set

$$E(G_i) := \{ \{j, k\} \subseteq [n] : j \neq k, j + k \in S_i \mod n \}.$$

Note that the intersection of distinct G_i , G_j is P free: since $|S_i \cap S_j| = 1$, if $\{a, b\}, \{a, c\} \in E(G_i) \cap E(G_j)$, then a + b = a + c so b = c.

We now count the number of edges in G_1, \ldots, G_n . Since $|S_i| = q + 1$, for each point $j \in [n]$, there are q + 1 choices for $k \in [n]$ such that $j + k \in S_i$. But then we have to avoid counting the same edge twice and loops, so the number of edges in G_i is

$$e(G_i) = \frac{n(q+1) - \#\text{loops counted for } G_i}{2}.$$

If $j \in [n]$ is even, then k = j/2 is the unique number in [n] such that $k + k = j \mod n$. If $j \in [n]$ is odd, then k = (n+j)/2 is the unique number in [n] such that $k + k = j \mod n$, as n is even. Hence, for each $j \in S_i$, there exists a unique $k \in [n]$ such that $k + k = j \mod n$, and thus

#loops counted for
$$G_i = |S_i| = q + 1$$
.

Since $q + 1 = (1 + o(1))n^{1/2}$, the number of edges in G_1, \ldots, G_n is

$$\sum_{i=1}^{n} e(G_i) = n \cdot \frac{n(q+1) - (q+1)}{2} = \left(\frac{1}{2} + o(1)\right) n^{5/2},$$

as $n \to \infty$.

The case for $n < m \le n^2$ is similar. Consider the finite projective plane P with n points defined above. Since $|S_i| = q+1 > \sqrt{n} \ge n^2/m$, we may further place a smaller projective plane P_i with n^2/m points inside each line S_i . Since each line of P_i has size roughly n/\sqrt{m} , each S_i contains roughly m/n lines, and thus we now have m small lines in total. Define G_i' on each small line the same way we defined G_i on S_i . Following the same line of calculations above, the construction of G_1', \ldots, G_m' now gives $\sum_{i=1}^m e(G_i) = (1/2 + o(1))\sqrt{m}n^2$, provided $m \le n^2$. This completes the proof.

3.4 Proof of Theorem 7

We now prove Theorem 7. Notice that we trivially have $f(m, n, r) \leq \phi(m, n, K_r)$, so it suffices to show the reverse inequality. That is, we need to show that there exists a blowup construction meeting the desired bound.

Let G_1, G_2, \ldots, G_m be graphs on [n] with no double K_r and $\sum_{i=1}^m e(G_i) = \phi(m, n, K_r)$.

Observe that any pair $\{i, j\} \subseteq [n]$ must be in some G_i , otherwise, we may add it to G_1 without creating a double K_r .

We call vertices v, v' clones if for all $u \in [n] \setminus \{v, v'\}$ and $i \in [m]$, the edge $\{u, v\} \in E(G_i)$ if and only if $\{u, v'\} \in E(G_i)$. Furthermore, we call $\{v, v'\}$ a light edge if $\{v, v'\}$ is in exactly one graph G_i .

We now apply Algorithm 1 to G_1, G_2, \ldots, G_m .

```
Algorithm 1 symmetrization algorithm
```

```
while \exists a light edge whose endpoints are not clones \mathbf{do}
among all vertices incident to such an edge, select a vertex v with maximum degree B_v \leftarrow collection of vertices sending a light edge to v that are not clones of v
while B_v \neq \emptyset \mathbf{do}
pick u \in B_v
j \leftarrow colour of the light edge from u to v
for 1 \leq i \leq m \mathbf{do}
if i \neq j then;
N_{G_i}(u) \leftarrow N_{G_i}(v)
else if i = j then
N_{G_i}(u) \leftarrow (N_{G_i}(v) \setminus \{u\}) \cup \{v\}
end if
end for
end while
```

Claim 3. Algorithm 1 terminates.

Proof. Notice that at the end of the 'while $B_v \neq \emptyset$ ' loop, every vertex sending a light edge to v is a clone of v. This implies v along with the set L_v of vertices receiving light edges from v induce a clique of size at least two in some G_i , and an empty graph in every other graph G_j with $j \neq i$. Moreover, any vertex $w \notin L_v$ sends edges to either all or none of the vertices in L_v , and if w is incident to L_v , then w sends edges to L_v in at least two graphs. It now follows that no light edge incident with a vertex in L_v will be picked again in an iteration of the out most while loop. Thus the algorithm can run through at most n/2 such iterations, and so it terminates.

Claim 4.
$$G'_1, G'_2, \ldots, G'_m$$
 do not contain a double K_r and $\sum_{i=1}^m e(G'_i) = \phi(m, n, K_r)$.

Proof. Note that we replace u by a clone of v in the for loop of Algorithm 1. Since $\{u, v\}$ remains a light edge in this step, u and v cannot both belong to a double K_r in the modified

graphs. Furthermore, any double K_r containing u after the for loop arises from a double K_r containing v prior to the for loop. But then G_1, G_2, \ldots, G_m contained no double K_r to begin with, so G'_1, G'_2, \ldots, G'_m do not contain a double K_r .

We now show that the algorithm does not reduce the number of edges. By our choice of v, we know $d(v) \geq d(u)$ for all $u \in B_v$ prior to the for loop. Hence, replacing u with a clone of v does not decrease the number of edge over a complete iteration of the inner while loop. Therefore, $\sum_{i=1}^{m} e(G'_i) = \phi(m, n, K_r)$.

Hence, the algorithm outputs graphs G'_1, G'_2, \ldots, G'_m with $\phi(m, n, K_r)$ edges and the additional property that light edges come in 'clone cliques.' We may thus partition the vertex set [n] into k disjoint sets V_1, V_2, \ldots, V_k , such that each V_i induces a clique of light edges from the same graph. Moreover, for distinct $i, j \in [k]$, define S_{ij} to be the set of all edges between V_i and V_j , and note that any edge in S_{ij} appears in at least two modified graphs. The sets S_{ij} now yield a k-blowup. Notice that if the pattern of the k-blowup contains a double K_r , then the original graphs G_1, G_2, \ldots, G_m must have contained a double K_r as well, contradiction. Thus the k-blowup is double K_r -free.

It remains to show that $k < R_M(K_r)$. For each edge $\{i, j\} \subseteq [k]$ in the pattern of the k-blowup, we assign an arbitrary distinct pair $\{a, b\} \subseteq L_{ij} \subseteq [m]$ to $\{i, j\}$. If $k \ge R_M(K_r)$, then there exists K_r in the pattern of the k-blowup colored by some distinct pair $\{a, b\} \subseteq [m]$. But then this implies the pattern of the k-blowup contains a double K_r , contradiction. This completes the proof.

3.5 Proof of Theorem 8

It is not hard to see that $\phi(2, n, K_3) = \binom{n}{2} + \lfloor n^2/4 \rfloor$: if G_1, G_2 is double triangle-free, then we have

$$e(G_1) + e(G_2) \le \binom{n}{2} + e(G_1 \cap G_2) \le \binom{n}{2} + e(n, K_3)$$

and so $\phi(2, n, K_3) \leq \binom{n}{2} + \lfloor n^2/4 \rfloor$. Taking $G_1 = K_n$ and $G_2 = K_{\lfloor n/2 \rfloor, \lceil n/2 \rceil}$ meets this bounds. The main result of this section is to show for all $n \geq 1$,

$$\phi(3, n, K_3) = \binom{n}{2} + \left\lfloor \frac{n^2}{2} \right\rfloor.$$

Let G_1, G_2, G_3 be double triangle-free. Define $H_k \subseteq G$ to be the graph with edges contained in at least k of the G_i 's and note that $e(G_1) + e(G_2) + e(G_3) = e(H_1) + e(H_2) + e(H_3)$. Thus it suffices to show that $e(H_2) + e(H_3) \le n^2/2$. Notice H_2 must not contain any triangles with two edges in H_3 , so

$$e(H_2) + e(H_3) \le \binom{n}{2} + e(H_3) - |\{\{u, v\} : u \ne v, N_{H_3}(u) \cap N_{H_3}(v) \ne \emptyset\}|.$$

Let H_3' be the graph with the same vertex set as H_3 and edge set $\{\{u,v\}: u \neq v, N_{H_3}(u) \cap N_{H_3}(v) \neq \emptyset\}$. It suffices to show that $n/2 \geq e(H_3) - e(H_3')$.

Let $d_1 \geq d_2 \geq \cdots \geq d_n$ and $f_1 \geq f_2 \geq \cdots \geq f_n$ each be the degree sequence of H_3 and H'_3 , respectively. We show that $f_i \geq d_i - 1$ for all i. Let v_i denote the vertex in H with degree d_i and u_i be the vertex in H with degree f_i . Let $S_i = |N_{H_3}(v_1) \cup \cdots \cup N_{H_3}(v_i)|$. Since

$$\sum_{u \in S_i} d_{H_3}(u) \ge d_1 + \dots + d_i,$$

we have that $|S_i| \ge i$. But then $S_i \setminus \{u_1, \dots, u_{i-1}\}$ is non-empty, and every $u \in S_i$ has degree $d_{H'_3}(u) \ge d_i - 1$. Hence, $f_i \ge d_i - 1$ for all i, which yields

$$e(H_3') = \frac{1}{2} \sum_{i=1}^{n} f_i \ge \frac{1}{2} \sum_{i=1}^{n} (d_i - 1) = e(H_3) - \frac{n}{2}.$$

This proves Theorem 8.

4 Concluding Remarks

- For Theorem 1, we may not be able to achieve the same result with smaller n. For example, consider F to be the bowtie graph, i.e. the 5-vertex graph with two triangles sharing a vertex. The n-vertex extremal graph for F is given by $K_{\lfloor \frac{n}{2} \rfloor, \lceil \frac{n}{2} \rceil}$ plus an edge when $n \geq 5$, otherwise it is the complete graph. For n = 5, the construction $G_1 = K_4, G_2 = K_5$ then shows that $\phi^*(2,5,F) > 2 \cdot \text{ex}(5,F)$. Fortunately, for non-bipartite F with |V(F)| = k, it is not hard to show $n \geq k^2$ is sufficient to avoid this issue.
- We note that Theorem 7 may be generalized to any family of non-bipartite graphs up to asymptotic error via Szemerédi's Regularity lemma
- One could ask for the analogous results for hypergraphs. That is, if F is an r-uniform hypergraph, let $\phi(m, n, F)$ be the maximum number of edges over m double F-free r-uniform hypergraphs on [n]. Again, we have $\phi(m, n, F) \geq \binom{n}{r} + (m-1) \cdot \operatorname{ex}(n, F)$. Another direction of generalization is to relax the constraint to no copies of F contained

in the intersection of k of the graphs G_1, G_2, \ldots, G_m . Many of the theorems and proofs also hold in this case. For instance, the proof of Theorem 4 applies for this generalization by merely changing the numbers.
